

How to Measure Anything in Project Management

Hubbard Decision Research 2 South 410 Canterbury Ct Glen Ellyn, Illinois 60137 www.hubbardresearch.com

Introduction

Applied Information Economics

AIE was applied initially to IT business cases. But over the last 20 years it has also been applied to other decision analysis problems in all areas of Business Cases, Performance Metrics, Risk Analysis, and Portfolio Prioritization.

IT

- Prioritizing IT portfolios
- Risk of software
 development
- Value of better information
- Value of better security
- Risk of obsolescence and optimal technology upgrades
- Value of infrastructure
- Performance metrics for the business value of applications

Business

- Movie / film project selection
- New product development
- Pharmaceuticals
- Medical devices
- Publishing
- Real estate

Engineering

- Risks of major engineering projects
- Risk of mine flooding

Government & Non Profit

• Environmental policy

٠

٠

- Sustainable agriculture
- Procurement methods
- Grants management

Military

- Forecasting battlefield fuel consumption
- Effectiveness of combat training to reduce roadside bomb / IED casualties
- R&D portfolios

- This is an introduction to basic concepts for measuring Project Management (PM).
- We will take a critical look at PM, how it is measured and then we will describe some solutions.
- We will treat this as an example of applying the ideas described in How to Measure Anything: Finding the Value of Intangibles in Business (HTMA).
- Some of the content are methods you can start using right away, others are aspirational and you should start on a path to master them.

I'm going to tend to focus on topics I don't think are covered quite enough in PM.

Question: Why Measure Projects?

Answer: The risk of doing it wrong is high!

- They are large and time consuming initiatives.
- Sometimes they have high visibility.
- Failure rates of projects from various sources: at least 10% maybe over 30% (failure includes cancellation but in some cases not meeting cost, schedule and deliverable goals).
- The cost of a failure can be greater than just wasted effort (loss in productivity, risk of customer loss, etc.).

The Current Most Popular Method

Using qualitative or "pseudo-quantitative" methods

Have you seen something like this applied to risks? (variously known as "heat map", "risk matrix", "probability and impact matrix" etc.)

		1	2	3	4	5	
		< 3%	3 to 15%	15% to 35%	35% to 65%	> 65%

Interaction with Others Increases Decision Confidence but Not Decision Quality: Evidence against Information Collection Views of Interactive Decision Making

Heath and Gonzalez

Abstract

We present three studies of *interactive decision making*, where decision makers interact with others before making a final decision alone. Because the theories of lay observers and social psychologists emphasize the role of information collection in interaction, we developed a series of tests of information collection. Two studies

Do "Scores" and "Scales" Work?

Unintended consequences of simple scoring methods

Researchers uncovered several unintended consequences of simple ordinal scales and using words for probabilities.

 David Budescu and Dick Heuer (separately) researched the "illusion of communication" regarding interpretations of verbal labels for probabilities.

Highly Likely	
Likely	
Probable	888 8
Unlikely	

10% 20% 30% 40% 50% 60% 70% 80% 90%

Craig R. Fox showed how arbitrary features of how scales are partitioned effects responses.

Example:

If "1" on a 5-point impact scale means "less than \$1 million loss", the share of that response is affected by the partition of *other* choices.

Do "Scores" and "Scales" Work?

Summarizing Research on Risk Matrices

- "Risk Matrices should not be used for decisions of any consequence."
 - Bickel et al. "The Risk of Using Risk Matrices", Society of Petroleum Engineers, 2014

- "...they can be 'worse than useless'"
 - Tony Cox "What's wrong with Risk Matrices" investigates various mathematical consequences of ordinal scales on a matrix.

The Only Risk Matrix You Need

Experts vs. Algorithms

What the research says about statistical methods vs. Subject Matter Experts

Paul Meehl assessed 150 studies comparing experts to statistical models in many fields (sports, prognosis of liver disease, etc.).

"There is no controversy in social science which shows such a large body of qualitatively diverse studies coming out so uniformly in the same direction as this one."

Philip Tetlock tracked a total of over 82,000 forecasts from 284 experts in a 20year study covering politics, economics, war, technology trends and more.

"It is impossible to find any domain in which humans clearly outperformed crude extrapolation algorithms, less still sophisticated statistical ones."

So Why Don't We Use More Quantitative Methods?

Commonly stated reasons for not using quantitative methods

The Three Misconceptions Behind Any Perceived "Immeasurable"

The Illusions of Immeasurability

	·
CONCEPT of Measurement	The definition of measurement itself is widely misunderstood.
OBJECT of Measurement	The thing being measured is not well defined.
METHOD of Measurement	Many procedures of empirical observation are misunderstood.

OBJECT of Measurement			

• What Measurement Really Means

It's not a point value.

<u>Measurement:</u> a quantitatively expressed reduction in uncertainty based on observation.

• What Measurement Really Means

Constructing a Distribution

- Uncertainty about "either/or" events are expressed as "discrete" probabilities (e.g. "35%).
- Uncertainty about continuous values can still be thought of as sets of discrete probabilities.

Calibrated Experts

"Overconfident professionals sincerely believe they have expertise, act as experts and look like experts. You will have to struggle to remind yourself that they may be in the grip of an illusion."

Daniel Kahneman, Psychologist, Economics Nobel

- Decades of studies show that most managers are statistically "overconfident" when assessing their own uncertainty.
- Studies also show that measuring *your own* uncertainty about a quantity is a general skill that <u>can be taught</u> with a *measurable* improvement.

The same training methods apply to the assessment of uncertain ranges for quantities like the duration of project, the impact of a major data breach, etc.

Monte Carlo: How to Model Uncertainty in Decisions

What Published Research Says (See sources slide for details)

- Psychologists showed that simple decomposition greatly reduces estimation error for estimating the most uncertain variables.
- In the oil industry there is a correlation between the use of quantitative risk analysis methods and financial performance.
- Data at NASA from over 100 space missions showed that Monte Carlo simulations and historical data beat softer methods for estimating cost and schedule risks.

Aggregating Uncertainty in Project Plans

Some project planning methods estimate durations based on "expected" time values. This is a classic "Flaw of Averages" problem (Sam Savage, Stanford).

- Four project components that all have to be completed before going to the next phase of the project.
- The duration of each task is 30 to 60 days (beta.inv(rand(),3,3)*30+30)
- What is the expected time before the next phase can start?
- What is the chance that the time is greater than 50 days?

Answers: 51 days, 60%

The Need for Simulation in Project Plans

- A project plan even just moderately more complicated requires a simulation for even the most basic risk analysis.
- Furthermore, the simulation must include inputs like benefits and discrete/conditional events to support project decisions comprehensively.

The Measurement Inversion

In a business case, the economic value of measuring a variable is usually inversely proportional to the measurement attention it typically gets.

- Initial cost
- Long-term costs
- Cost saving benefit other than labor productivity
- Labor productivity
- Revenue enhancement
- Technology adoption rate
- Project completion

Most Measured

Least Measured

Increasing Cost and Value Information

If we can model uncertainty about decisions, we can compute the value of information.

The Three Misconceptions Behind Any Perceived "Immeasurable"

The Object of Measurement

CONCEPT of Measurement	The definition of measurement itself is widely misunderstood.
OBJECT of Measurement	The thing being measured is not well defined.

- 1. Why do you care? (What decision could depend on the outcome of this measurement?)
- 2. What do you see when you see more of it? (Describe it in terms of observable consequences, then units of measure.)
- 3. How much do you know about it now?
- 4. At what point will the value make a difference?
- 5. How much is additional information worth?

If you can answer the first three, you can usually compute the last two.

- We can think through three categories of decisions. Your specific decision will depend on where you are in the project.
- Your initial business case is not "throw away." It should stay with the project for its lifespan.

When Examples of Decisions

- Before Should I engage in this specific effort?
- During Should I change course including: stop the project, reduce the features, change the managers, etc.
- After Do I need to do more? (Also informs future project approval decisions.)

The Object of Measurement

A General Procedure for Measurement

AIE quantifies and then optimizes decisions by focusing measurements where it matters most.

- When the inputs to a decision model are uncertain, the output should be uncertain this is what simulations are for.
- Is this a "good" distribution or a "bad" one? How would you know?

The Psychology of Risk Aversion

Factor

• Why Does Our Risk Tolerance Change?

Decision makers are also inconsistent regarding their own aversion to risk.

Expert Inconsistency in Estimates & Risks

- Adjusting for risk causes some previously-acceptable projects to be rejected.
- Also, some low return but low risk projects would now be acceptable.
- More projects with "intangible" benefits are now economically justified.
- The net result: A completely reshuffled deck of IT project approvals

The Object of Measurement

One Decision During a Project: Managing Scope

- One reason for "scope creep" may be that the true cost of adding additional features to software in development is greatly underestimated.
- If costs are computed at all, they usually consider only initial development.

Actual Case: Cost of Adding Feature Which Extends Delivery by One Month

The Three Misconceptions Behind Any Perceived "Immeasurable"

The Method of Measurement

METHOD of Measurement	Many procedures of empirical observation are misunderstood.

Testing Measurement Intuition

A Sample of 5

- Suppose you are extremely uncertain about how much time per day is spent in some activity in a company of 10,000 people.
- Imagine you randomly sample 5 people out of a company and they spend an amount of time in this activity as shown by the data points below.
- Is this statistically significant?
- Is it possible to estimate the chance the median time spent per person per day is between 15 and 40 minutes?

Minutes per day in activity X

Intuitions About Samples Are Wrong

- There are widely held misconceptions about probabilities and statistics especially if they vaguely remember some college stats.
- These misconceptions lead many experts to believe they lack data for assessing uncertainties or they need some ideal amount before anything can be inferred.

"Our thesis is that people have strong intuitions about random sampling...these intuitions are wrong in fundamental respects...[and] are shared by naive subjects and by trained scientists" Amos Tversky and Daniel Kahneman, Psychological Bulletin, 1971

The "Math-less" Statistics Table

Approximate 90% Confidence Interval					
Sample Size	N th largest & smallest sample value				
5	1 st				
8	2 nd				
11	3 rd				
13	4 th				
16	5 th				
18	6 th				
21	7 th				
23	8 th				

- Simple Measurement Takeaway This table makes estimating a 90% confidence interval of a population median easy.
- <u>The Rule of Five:</u> There is a 93.75% chance that the median of any population is between the smallest and largest values in a random sample of five.
- This table expands on the Rule of Five. If you take 16 random samples of something, the 5th largest and 5th smallest values of that sample set approximate a 90% confidence interval.

How Much Samples Can Tell Us

The graph below shows the average of relative reduction in uncertainty as sample sizes increase by showing the 90% CI getting narrower and narrower with each sample according to the student-t method.

With a few samples, there is still high uncertainty but...

... each new sample reduces uncertainty a lot and the first few samples reduce uncertainty the most when initial uncertainty is high.

As number of samples increases, the 90 % CI get much narrower, but each new sample reduces uncertainty only slightly and beyond about 30 samples you need to quadruple the sample size to cut the error in half.

Useful Assumptions About Measurement

If your measurement is challenged with limited or messy data, consider the following:

• It's been measured before.

- . You have more data than you think.
- You need less data than you think.

"It's amazing what you can see when you look" Yogi Berra

The Distribution of Canceled Projects vs. Duration

- Duration alone is the single best predictor of project cancellation.
 (Duration is also affected by several other factors normally associated with project failure – sponsorship, proper project management, quality and avoiding rework, etc.)
- Duration seems to follow a "Poisson" distribution – as if "cancellation events" are evenly distributed through time and longer projects are more likely to contain one of these events.

When do Projects Get Cancelled?

If you need a more detailed model for cancellation, consider data regarding when cancellation occurs in your model.

Data From: J. McManus; T. Wood-Harper "Understanding the Sources of Information Systems Project Failure" *Management Services*, Autumn 2007 - A Study of 214 project from 1998 to 2005 in EU organizations.

Best Predictors of Success?

For a large government client, we analyzed a large portfolio of projects looking for project-related factors that predicted a positive ROI.

Success Factor	Percent Point in P(ROI>0)*
Level of Sponsor/Champion meets or exceeds requirements for project scope	5% to 30%
Duration less than one budget cycle	Up to 22%
Technology related: Age of technology, Used by competitors, etc.	2% to 10%
Vendor related: Currently used & proven vendors, track record with vendor	3 to 8%

*Positive ROI meant it was not canceled and even if cost and schedule went over, net benefits were still positive. The actual analysis was a logistic regression where the baseline P(ROI>0) was 55%.

You Have More Data Than You Think

You have a lot of data in the organization. Even samples of some of this data can be revealing indicators of communication, involvement, etc.

- Calendars
- Working group discussion threads
- Project deliverables
- Frequency and cost of errors/rework
- Utilization of various systems
- Turnover
- Milestones on schedule

Measuring and Removing Inconsistency

Methods that statistically "smooth" estimates of experts show reduced error in several studies for many different kinds of problems.

Reduction in Errors

What Project Management Should Really Manage

Project completion is consistently a high value measurement, followed by adoption and benefits. Therefore:

- <u>Manage cancellation by managing duration</u> Project management should be about managing duration to avoid uncontrolled cancelation events, and ensuring the utility of the outcome.
- <u>Manage user adoption and benefits</u> User involvement will generally increase project benefits, which is also a responsibility of the project manager.
- <u>Fail early</u> Someone, if not project managers, needs to be in the position of asking, "Do we still need this?" based on changing external factors and evolving knowledge of the project difficulty.

Project Risk Considerations

Project managers tend to be internally focused – but many risks are upper-management driven and even exogenous to the organization.

Many of the following can be gathered in large quantities internally or from publicly-available historical data.

- Team availability, pulled away to "emergency" work
- Staff turnover at all levels
- Loss of project sponsor/champion
- Merger, divestiture of the business
- Competing products, technology obsolescence
- Cost-cutting due to business losses
- Loss of key vendor
- New legislation, political risk
- Unanticipated technical hurdles

Using Risk Analysis to Improve Projects

If the Risk is significant (it usually is), consider doing the following:

- Reduce the size and functionality of the proposed system focus on fewer high-return features.
- Define "Independently Justifiable Phases" (IJP) and quicker, iterative development methods (Agile, Lean, etc.).
- Wait until specific uncertainties in the environment subside e.g. major mergers, reengineering, etc.
- Wait to tackle big projects until proper skills are developed and methods are in place.
- "Off the Shelf" looks better when risk is considered.
- Invest more on a proper economic analysis of the largest project investments this should reduce uncertainty about critical quantities.
- Include deferred benefits in any estimate of scope creep costs.

Value of Quantitative Analysis for Projects

- The cost of analysis routinely comes in below 1% and has always been under 2% of the investment size including initial training.
- Considering the risk of bad project approval decisions, this would be entirely appropriate (and some types of projects exceed this).
- Quantitative analysis is not necessarily more time consuming that some qualitative methods. (One of the reasons this analysis is efficient is we conduct a Value of Information Analysis we only measure what is economically justified).
- Using the standard information value calculation for the value of AIE analysis, quantitative analysis
 itself was the best investment of all the IT investments we analyzed very conservative measures of
 payoffs put \$20 to every \$1 spent on AIE.

What to Do Next

Things you can do now or very soon:

- Drop the use of "scores" and "matrices" define actual observables in units of measure and quantify risk with probabilities.
- Identify the specific decisions you are trying to support.
- Build a decision model/business case for the project and keep it for the life cycle of the project and what it builds.
- Get calibrated so you can quantify your uncertainty.

Things to strive toward (the effort is easily justified for large projects or even small but frequent projects):

- Learn to model the uncertainty of a decision in a simulation evolve the model with more detail over time.
- Learn to compute the value of information.
- Learn a few more simple statistical methods especially models for what experts usually estimate.
